A

FOREWORD

This document describes version 1.22 of the E-ACSL specification language. It is based on the ACSL specification language [2]. Features of both languages may still evolve in the future, even if we do our best to preserve backward compatibility. In particular, some features are considered *experimental*, meaning that their syntax and semantics is not yet fixed. These features are marked with EXPERIMENTAL.

Acknowledgements

We gratefully thank all the people who contributed to this document: Patrick Baudin, Bernard Botella, Thibaut Benjamin, Loïc Correnson, Pascal Cuoq, Basile Desloges, Johannes Kanig, André Maroneze, Fonenantsoa Maurica, David Mentré, Benjamin Monate, Yannick Moy and Virgile Prevosto.

This work has been initially supported by the 'Hi-Lite' FUI project (FUI AAP 9).

Introduction

This document is a reference manual for the E-ACSL implementation provided by the E-ACSL plugin [11] of the Frama-C framework [7], version 31.0 (Gallium). E-ACSL is an acronym for "Executable ANSI/ISO C Specification Language". It is an "executable" subset of ACSL [2] implemented [3] in the Frama-C platform [7]. Contrary to ACSL, each E-ACSL specification is executable: it may be evaluated at runtime.

In this document, we assume that the reader has a good knowledge of both ACSL [2] and the ANSI C programming language [8, 9].

1.1 Organization of this document

This document is organized in the very same way that the reference manual of ACSL [2].

Instead of being a fully new reference manual, this document points out the differences between E-ACSL and ACSL. Each E-ACSL construct which is not pointed out must be considered to have the very same semantics than its ACSL counterpart. For clarity, each relevant grammar rules are given in BNF form in separate figures like the ACSL reference manual does. In these rules, constructs with semantic changes are displayed in blue.

Not all of the features mentioned in this document are currently implemented in the FRAMA-C's E-ACSL plug-in. Those who aren't yet are signaled as in the following line:

This feature is not currently supported by Frama-C's E-ACSL plug-in.¹

As a summary, Figure 1.1 synthetizes main features that are not currently implemented into the Frama-C's E-ACSL plug-in.

1.2 Generalities about Annotations

No difference with ACSL.

1.3 Notations for grammars

No difference with ACSL.

¹ Additional remarks on the feature may appear as footnote.

typing	mathematical reals
terms	truth values \true and \false
	functional updates
	irrational numbers
	built-in function \length over arrays
	conversions of structure to structure
	t-sets
	abstractions
	\max and \min
	hybrid functions
	labeled memory-related built-in functions
	finite sets
	finite lists
	\exit status
predicates	let bindings of predicates
	unguarded quantifications over small types
	quantifications over pointers and enums
	iterators
	comparisons of unions and structures
	t-sets
	hybrid predicates
	labeled memory-related built-in predicates
	dangling pointers \dangling
clauses	decreases clauses
	assigns clauses
	allocation and deallocation clauses
	abrupt clauses
	reads clauses
annotations	behavior-specific annotations (introduced by for)
	loop assigns
	loop allocations
	lemmas
	inductive predicates
	axiomatic definitions
	polymorphic logic types
	concrete logic types
	specification modules
	data invariants
	model variables and model fields
	volatile variables

Figure 1.1: Summary of not-yet-implemented features.

2.1 Lexical rules

No difference with ACSL.

2.2 Logic expressions

No difference with ACSL, but the quantifications must be guarded.

More precisely, the grammars of terms and binders presented respectively Figures 2.1 and 2.3 are the same than the ones of ACSL, while Figure 2.2 presents the grammar of predicates. The only differences introduced by E-ACSL with respect to ACSL are the fact that the quantifications that must be guarded and the introduction of iterators.

Quantification

The general form of quantifications (called generalized quantifications below), as described in Fig. 2.2, is restricted to a few *finite enumerable types*: the types of bound variables must be C integer types, enum types, pointer types, or their aliases.

Generalized quantification over large types (for instance, types containing 2^{32} elements). are unlikely evaluated efficiently at runtime.

In addition to generalized quantifications, a restricted form of guarded quantifications described in Fig. 2.4 is also recognized for (possibly infinite) enumerable types (typically, integer). In guarded quantifications, each bound variable must be guarded exactly once and, if its bounds depend on other bound variables, these variables must be guarded earlier or guarded by the same guard. Additionnally, guards are limited to bound variables, meaning that the only allowed identifiers id are variable identifiers enclosed in the binder list.

Guarded quantifications over pointer types and enum types are not yet implemented.

Example 2.1 The following predicates are (labeled) guarded quantifications:

```
- sorted: \forall integer i, j; 0 <= i <= j < len ==> a[i] <= a[j] - is_c: \exists u8 *q; p <= q < p + len && *q == (u8)c
```

Iterator quantification

For iterating over other data structures, E-ACSL introduces a notion of *iterators* over types that are introduced by a specific construct which attaches two sets — namely nexts and guards — to a binary predicate over a type τ . This construct is described by the grammar of Figure 2.5. For a type τ , nexts is a set of terms, and guards a set of predicates of the same cardinal. Each term in nexts is a function

```
literal
                \true
                         \false
                                                    boolean constants
          ::=
                integer
                                                    (lexical) integer constants
                real
                                                    (lexical) real constants
                string
                                                    (lexical) string constants
                character
                                                    (lexical) character constants
  bin-op
                            <= |
                == | != |
                                                    boolean operations
                8.8
                << | >>
                & | | --> |
                                                    bitwise operations

         terms
                  ::=
     predicates
                       predicate (, predicate)*
                  ::=
```

Figure 2.5: Grammar of iterator declarations

taking an argument of type τ and returning a value of type τ which is a successor of its argument. Each predicate in the set guards takes an element of type τ , and is valid (resp. invalid) to indicate that the iteration should continue on the corresponding successor (resp. stop at the given argument).

Furthermore, the guard of a quantification using an iterator must be the predicate given in the definition of the iterator. This abstract binary predicate takes two arguments of the same type. One of them must be unnamed by using a wildcard (character underscore '_'). The unnamed argument must be bound to the quantifier, while the other corresponds to the term from which the iteration begins.

Example 2.2 The following example introduces binary trees and a predicate which is valid if and only if each value of a binary tree is even.

```
struct btree {
  int val;
  struct btree *left, *right;
};

/*@ iterator access(_, struct btree *t):
  @ nexts t->left, t->right;
  @ guards \valid(t->left), \valid(t->right); */

/*@ predicate is_even(struct btree *t) =
  @ \forall struct btree *tt; access(tt, t) ==> tt->val % 2 == 0; */
```

2.2.1 Operators precedence

No difference with ACSL.

Figure 2.6 summarizes operator precedences.

class	associativity	operators
selection	left	[···] -> .
unary	right	!~+- * & (cast) sizeof
multiplicative	left	* / %

Figure 2.6: Operator precedence

2.2.2 Semantics

No difference with ACSL, but undefinedness and same laziness than C.

More precisely, while ACSL is a 2-valued logic with only total functions, E-ACSL is a 3-valued logic with partial functions since terms and predicates may be "undefined".

In this logic, the semantics of a term denoting a C expression e is undefined if e leads to a runtime error. Consequently the semantics of any term t (resp. predicate p) containing a C expression e leading to a runtime error is undefined if e has to be evaluated in order to evaluate t (resp. p).

Example 2.3 The semantics of all the below predicates are undefined:

```
- 1/0 == 1/0
- f(*p) for any logic function f and invalid pointer p
```

Furthermore, C-like operators &&, ||, and _ ? _ : _ are lazy like in C: their right members are evaluated only if required. Thus the amount of undefinedness is limited. Consequently, predicate p ==> q is also lazy since it is equivalent to p ==> q. It is also the case for guarded quantifications since guards are conjunctions and for ternary condition since it is equivalent to a disjunction of implications.

Example 2.4 All the predicates below are well defined. The first, second and fourth predicates are invalid, whereas the third one is valid:

```
-\false && 1/0 == 1/0
-\forall integer x, -1 <= x <= 1 ==> 1/x > 0
-\forall integer x, 0 <= x <= 0 ==> \false ==> -1 <= 1/x <= 1
-\exists integer x, 1 <= x <= 0 && -1 <= 1/0 <= 1
```

In particular, the second one is invalid since the quantification is in fact an enumeration over a finite number of elements, it amounts to 1/-1 > 0 && 1/0 > 0 && 1/1 > 0. The first atomic proposition is invalid, so the rest of the conjunction (and in particular 1/0) is not evaluated. The fourth one is invalid since it is an existential quantification over an empty range.

A contrario the semantics of the predicates below is undefined:

```
-1/0 == 1/0 \&\& false

--1 <= 1/0 <= 1 ==> true

- exists integer x, <math>-1 <= x <= 1 \&\& 1/x > 0
```

Furthermore, casting a term denoting a C expression e to a smaller type τ is undefined if e is not representable in τ .

Example 2.5 Below, the first term is well-defined, while the second one is undefined.

```
(char) 127(char) 128
```

Handling undefinedness in tools It is the responsibility of each tool which interprets E-ACSL to ensure that an undefined term is never evaluated. For instance, it may exit with a proper error message or, if it generates C code, it may guard each generated undefined C expression in order to be sure that they are always safely used.

The E-ACSL plug-in of FRAMA-C generates such guards. Yet, a few guards are still missing.

This behavior is consistent with both ACSL [2] and mainstream specification languages for runtime assertion checking like JML [10]. Consistency means that, if it exists and is defined, the E-ACSL predicate corresponding to a valid (resp. invalid) ACSL predicate is valid (resp. invalid). Thus it is possible to reuse tools interpreting ACSL (e.g., Frama-C's Eva [4] or WP [1] in order to interpret E-ACSL, and it is also possible to perform runtime assertion checking of E-ACSL predicates in the same way than JML predicates. Reader interested by the implications (especially issues) of such a choice may read the articles of Patrice Chalin on that topic [5, 6].

2.2.3 **Typing**

No difference with ACSL.

2.2.4 Integer arithmetic and machine integers

No difference with ACSL.

2.2.5 Real numbers and floating point numbers

No difference with ACSL, but no quantification over real numbers and floating point numbers.

Exact real numbers and even operations over floating point numbers are usually difficult to implement. Thus, most tools may not support them (or may support them partially).

More precisely, most real numbers are not representable at runtime with an infinite precisions. Consequently, most operations over them (e.g., equality) cannot be computed at runtime with an arbitrary precision. In such cases, it is the responsibility of each tool which interprets E-ACSL to specify the level of precision (e.g., $1e^{-6}$) up to which it is sound, and/or to emit undefinitive verdicts (e.g., "unknown").

Only floating point numbers (e.g., 0.1f), rationals numbers (in \mathbb{Q}) and operations over them are supported by the E-ACSL plug-in. Real numbers that are irrational numbers are not supported.

2.2.6 C arrays and pointers

No difference with ACSL.

Ensuring validity of memory accesses is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.2.7 Structures, Unions and Arrays in logic

No difference with ACSL.

Logic arrays without an explicit length are usually difficult to implement. Thus, most tools may not support them (or may support them partially).

The following constructs are currently not supported by the E-ACSL plug-in:

- built-in function \length;
- comparisons of unions and structures;
- functional updates;
- conversions of structure to structure.

2.3 Function contracts

No difference with ACSL, but no clause terminates.

Figure 2.7 shows the grammar of function contracts. This is a simplified version of ACSL one without terminates clauses. Section 2.5 explains why E-ACSL has no terminates clause.

2.3.1 Pre- and Post- state

No difference with ACSL.

Figure 2.8 summarizes the grammar extension of terms with \old and $\result.$

```
function-contract
                           requires-clause*
                            decreases-clause? simple-clause*
                           named-behavior* completeness-clause*
                           check | admit
        clause-kind
                     ::=
                           clause-kind? requires pred ;
    requires-clause
                     ::=
  decreases-clause
                           decreases term (for ident)? ;
                     ::=
                           assigns-clause | ensures-clause
      simple-clause
                     ::=
                           allocation-clause | abrupt-clause
    assigns-clause
                     ::=
                           assigns locations ;
         locations
                           locations-list | \nothing
                     ::=
     locations-list
                           location (, location) *
                     ::=
          location
                     ::=
                           tset
     ensures-clause
                           clause-kind? ensures pred ;
                     ::=
   named-behavior
                           behavior id : behavior-body
                     ::=
                           assumes-clause* requires-clause* simple-clause*
    behavior-body
                     ::=
    assumes-clause
                     ::=
                           assumes pred ;
completeness\hbox{-} clause
                            complete behaviors (id \ (, id)^*)^?
                     ::=
                            disjoint behaviors (id \ (, id)^*)^?
```

Figure 2.7: Grammar of function contracts

Figure 2.8: $\old and \result in terms$

2.3.2 Simple function contracts

No difference with ACSL.

assigns is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.3.3 Contracts with named behaviors

No difference with ACSL.

2.3.4 Memory locations and sets of terms

No difference with ACSL, but ranges and set comprehensions are limited in order to be finite. Figure 2.9 describes the grammar of sets of terms. There are two differences with ACSL:

- ranges necessarily have lower and upper bounds;
- a guard for each binder is required when defining set comprehension. The requested constraints for guards are the very same than the ones for quantifications.

```
range
              ::=
                    term .. term
             ::=
      tset
                                                           empty set
                    \empty
                    tset -> id
                         . id
                    tset
                     tset
                    & tset
                    tset [ tset ]
                        [ range ]
                    ( range )
                                                           a range as a set of integers
                                                           union of location sets
                    \union ( tset (, tset)*
                                                           intersection of location sets
                    \inter ( tset (, tset)* )
                    tset + tset
                    ( tset
                      tset | binders ; constraints }
                                                           set comprehension
                      (term (, term)^*)^? }
                                                           explicit set
                                                           implicit singleton
                                                           set inclusion
      pred
              ::=
                    \subset ( tset , tset )
                    term \in tset
                                                           set membership
                   guards (&& pred)?
constraints
```

Figure 2.9: Grammar for sets of terms

Example 2.6 The set { $x \mid \text{integer } x; 0 \le x \le 10 \&\& x % 2 == 0}$ denotes the set of even integers between 0 and 10.

Ranges are currently only supported in memory built-ins described in Section 2.7.1, 2.13 and 2.14.

Example 2.7 The predicate \vert id (&t[0 .. 9]) is supported and denotes that the ten first cells of the array t are valid. Writing the term &t[0 .. 9] alone, outside any memory built-in, is not yet supported.

2.3.5 Default contracts, multiple contracts

No difference with ACSL.

2.4 Statement annotations

2.4.1 Assertions

No difference with ACSL.

Figure 2.10 summarizes the grammar for assertions.

```
{ C-declaration*
C-compound-statement
                               C-statement* assertion^+ }
          C-statement
                               assertion
                        ::=
                               C-statement
        assertion-kind
                               assert
                                                              assertion
                        ::=
                               clause-kind
                                                              non-blocking assertion
                         ::=
                               /∗@ assertion-kind pred ;
             assertion
                               */
                               /*@ for id (, id)* :
                               assertion-kind pred;
                               */
```

Figure 2.10: Grammar for assertions

2.4.2 Loop annotations

No difference with ACSL, but loop invariants lose their inductive nature.

Figure 2.11 shows the grammar for loop annotations. There is no syntactic difference with ACSL.

```
/*@ loop-annot */
    statement
                 ::=
                       C-iteration-statement
   loop-annot
                       loop-clause* loop-behavior*
                 ::=
                       loop-variant?
   loop-clause
                       loop-invariant | loop-assigns
                 ::=
                       loop-allocation
loop-invariant
                       clause-kind?
                 ::=
                       loop invariant pred ;
 loop-assigns
                       loop assigns locations ;
                 ::=
                       for id (, id)* : loop\text{-}clause*
loop-behavior
                                                            annotation for behavior id
                 ::=
  loop-variant
                       loop variant term ;
                 ::=
                                                            variant for relation id
                       loop variant term for id ;
```

Figure 2.11: Grammar for loop annotations

loop allocation and loop assigns are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

Loop invariants

The semantics of loop invariants is the same than the one defined in ACSL, except that they are not inductive. More precisely, if one does not take care of side effects (the semantics of specifications about side effects in loop is the same in E-ACSL than the one in ACSL), a loop invariant I is valid in ACSL if and only if:

- I holds before entering the loop; and
- if I is assumed true in some state where the loop condition c is also true, and if the execution of
 the loop body in that state ends normally at the end of the body or with a "continue" statement,
 I is true in the resulting state.

In E-ACSL, the same loop invariant I is valid if and only if:

- I holds before entering the loop; and
- if the execution of the loop body in that state ends normally at the end of the body or with a "continue" statement, I is true in the resulting state.

Thus the only difference with ACSL is that E-ACSL does not assume that the invariant previously holds when one checks that it holds at the end of the loop body. In other words a loop invariant I is equivalent to putting an assertion I just before entering the loop and at the very end of the loop body.

Example 2.8 In the following, brearch (t, n, v) searches for element v in array t between indices 0 and n-1.

```
/*@ requires n >= 0 && \valid(t+(0..n-1));
  @ assigns \nothing;
  @ ensures -1 <= \result <= n-1;</pre>
  @ behavior success:
  @
      ensures \result >= 0 ==> t[\result] == v;
  @ behavior failure:
      assumes t_is_sorted : \forall integer k1, int k2;
          0 \le k1 \le k2 \le n-1 \Longrightarrow t[k1] \le t[k2];
      ensures \result == -1 ==>
  9
        \forall integer k; 0 <= k < n ==> t[k] != v;
  (a
  a * /
int bsearch(double t[], int n, double v) {
  int 1 = 0, u = n-1;
  /*@ loop invariant 0 <= 1 && u <= n-1;
    @ for failure: loop invariant
        \forall integer k; 0 <= k < n ==> t[k] == v ==> 1 <= k <= u;
    @*/
  while (1 <= u ) {
    int m = 1 + (u-1)/2; // better than (1+u)/2
    if (t[m] < v) l = m + 1;
    else if (t[m] > v) u = m - 1;
    else return m;
  return -1:
```

In E-ACSL, this annotated function is equivalent to the following one since loop invariants are not inductive.

```
/*@ requires n >= 0 && \valid(t+(0..n-1));
@ assigns \nothing;
@ ensures -1 <= \result <= n-1;</pre>
```

```
@ behavior success:
      ensures \result >= 0 ==> t[\result] == v;
  (a
  @ behavior failure:
      assumes t_is_sorted : \forall integer k1, int k2;
  @
          0 \le k1 \le k2 \le n-1 \Longrightarrow t[k1] \le t[k2];
  (a
      ensures \result == -1 ==>
  (a
        \forall integer k; 0 <= k < n ==> t[k] != v;
  @*/
int bsearch(double t[], int n, double v) {
  int 1 = 0, u = n-1;
  /*@ assert 0 <= 1 && u <= n-1;
    @ for failure: assert
        \forall integer k; 0 <= k < n ==> t[k] == v ==> 1 <= k <= u;
    (a
    @ * /
  while (1 <= u ) {
    int m = 1 + (u-1)/2; // better than (1+u)/2
    if (t[m] < v) l = m + 1;
    else if (t[m] > v) u = m - 1;
    else return m;
    /*@ assert 0 <= 1 && u <= n-1;
      @ for failure: assert
          \forall integer k; 0 <= k < n ==> t[k] == v ==> 1 <= k <= u;
      @*/;
  return -1;
```

General inductive invariant

The syntax of this kind of invariant is shown Figure 2.12.

```
assertion ::= /*@ clause-kind? invariant pred ; */
| /*@ for id (, id)* : clause-kind? invariant pred ; */
```

Figure 2.12: Grammar for general inductive invariants

In E-ACSL, a general inductive invariant may be written everywhere in a loop body, and is exactly equivalent to writing an assertion.

2.4.3 Built-in construct \at

No difference with ACSL, but no forward references.

The construct \at(t,id) (where id is a regular C label, a label added within a ghost statement or a default logic label) follows the same rule than its ACSL counterpart, except that a more restrictive scoping rule must be respected in addition to the standard ACSL scoping rule:

- when evaluating $\at(t,id)$ at a propram point p, the program point p' denoted by id must be reached before p in the program execution flow; and
- when evaluating $\at(t,id)$, for each C left-value x that contributes to the definition of a (non-ghost) logic variable involved in t, the equality $\at(x,id) == \at(x,Here)$ must hold, i.e. the value of x must not be modified between the program points id and Here.

Below, the first example illustrates the first constraint, whereas the second example illustrates the second constraint.

Example 2.9 In the following example, both assertions are accepted and valid in ACSL, but only the first one is accepted and valid in E-ACSL since evaluating the term $\at (*q, Here)$), L1) at L2 requires to evaluate the term $\at (*q, Here)$ at L1: that is forbidden since L1 is executed before L2.

```
/*@ requires \valid(p+(0..1));
  @ requires \valid(q);
  @*/
void f(int *p, int *q) {
    *p = 0;
    *(p+1) = 1;
    *q = 0;
    L1: *p = 2;
    *(p+1) = 3;
    *q = 1;
    L2:
    /*@ assert (\at(*(p+\at(*q,L1)),Here) == 2); */
    /*@ assert (\at(*(p+\at(*q,Here)),L1) == 1); */
    return;
}
```

Example 2.10 In the following example, the first assertion is supported, while the second one is not supported. Indeed, in the second assertion, the guard defining the logic variable u depends on n whose value is modified between L1 and L2.

```
main(void) {
 int m = 2;
 int n = 7;;
L1: ;
 n = 4;
L2:
  /*@ assert
      \let k = m + 1;
     \exists integer u; 9 <= u < 21 &&
     \forall integer v; -5 < v <= (u < 15 ? u + 6 : k) ==>
       \at(n + u + v > 0, K); */;
  /*@ assert
     \let k = m + 1;
      \exists integer u; n <= u < 21 && // [u] depends on [n]
      \forall integer v; -5 < v <= (u < 15 ? u + 6 : k) ==>
       return 0;
```

Any $\actor{}$ construct involving a logic variable whose definition depends on a C variable is currently unsupported by plug-in E-ACSL.

Example 2.11 The \old construct (special case of \at) of the following example is not yet supported since the guard of the quantified variable i depends on the C variable n in the definition of its upper bound.

```
/*@ ensures \forall int i; 0 <= i < n-1 ==> \old(t[i]) == t[i+1]; */
void reverse(int *t, int n);
```

2.4.4 Statement contracts

No difference with ACSL.

Figure 2.13 shows the grammar of statement contracts.

```
statement
                        ::=
                               / ★ @ statement-contract ★ / statement
                              (for id (, id)^* :)^? requires-clause*
  statement-contract
                        ::=
                               simple-clause-stmt* named-behavior-stmt*
                               completeness-clause*
   simple-clause-stmt

Figure 2.14: Grammar for global logic definitions

2.6.1 Predicate and function definitions

No difference with ACSL.

2.6.2 **Lemmas**

No difference with ACSL.

Lemmas are verified before running the function main but after initializing global variables.

2.6.3 Inductive predicates

EXPERIMENTAL

No difference with ACSL.

Figure 2.15 presents the grammar of inductive predicates.

Figure 2.15: Grammar for inductive predicates

Inductive predicates are usually difficult to implement, since they require a fix-point calculation, which is not viable in practice. Thus, most tools may not support them (or may support them partially). Inductively defined predicates in all their generality are thus not monitorable; however a restricted subset as described below is supported.

Notably this subset includes predicates whose constructors (indcase in the above grammar) have a form corresponding to definite Horn clauses (http://en.wikipedia.org/wiki/Horn_clause): for an inductively defined n-ary predicate P its constructors are of the form \forall ...; $h_1 ==> \ldots ==> h_k ==> P(a_1, \ldots, a_n)$, with the following restrictions:

- every occurrence of P (apart from the conclusion P (a_1, \ldots, a_n) is at the root of one of the hypotheses. This implies that it cannot occur in negated form. h_1, \ldots, h_k .
- all the arguments a_1, \ldots, a_n of the conclusion are *simple*, i.e. they are either constants or (universally) quantified variables.
- any quantified variable occurring in one of the hypotheses h_1, \ldots, h_k occurs in the conclusion.

Let us call this the *simple subset* of supported predicates.

Example 2.12 (supported) This definition belongs to the simple subset as described above.

```
inductive gcd(integer n, integer m, integer r) {
   case gcd_zero: \forall integer x; gcd(x, 0, x);
   case gcd_S: \forall integer x, y, z;
      y != 0 ==> gcd(y, x % y, z) ==> gcd(x, y, z);
}
```

For the constructor gcd_zero the chain of implications is empty, which is permissible; all of the conclusion's arguments are either quantified variables (x) or constants (0).

The constructor gcd_S has three quantified variables, which occur in the hypotheses as well as in the conclusion. The conclusion has the correct form, as all of its arguments are quantified variables. The predicate gcd occurs (positively) as the root of a hypothesis.

Example 2.13 (unsupported) This definition does not belong to the simple subset. The quantified variable c occurs in one of the hypotheses but does not appear in the conclusion.

```
inductive eq(integer x, integer y) {
  case c: \forall integer a, b, c; a == c ==> b == c ==> eq(a, b);
}
```

Example 2.14 (supported) This definition belongs to the simple subset as described above. In the constructor zero, the quantified variable does not occur in the conclusion. This poses no problem as long as it does not occur in any conclusion.

```
inductive even(integer x) {
  case zero: \forall integer a; even(0);
  case pos: \forall integer a; a >= 2 ==> even(a-2) ==> even(a);
  case neg: \forall integer a; a <= -2 ==> even(a+2) ==> even(a);
}
```

Example 2.15 (unsupported) This definition does not belong to the simple subset, as P occurs in a hypothesis but not at its root, as it is negated.

```
inductive even(integer x) {
  case zero: \forall integer a; even(0);
  case pos: \forall integer a; a >= 2 ==> !even(a-1) ==> even(a);
  case neg: \forall integer a; a <= -2 ==> !even(a+1) ==> even(a);
}
```

This simple subset is extended in some important ways giving rise to the *extended subset* of supported predicates:

- there may be \let expressions inserted in the chain of implications.
- one of P's arguments may be *complicated*, i.e. it does not need to be a constant or a quantified variable. The position of the complicated argument has to be identical for all the constructors.
- the quantified variables occurring in the formulas have to obey certain boundness conditions, such as: a quantified variable occurring in the complicated argument, needs to be bound first by a recursive occurrence of P in a hypothesis.

As these conditions (especially the boundness conditions) are too intricate to explain here, let's consider a few more examples in order to convey an intuition for which inductive definitions are supported and which are not.

Example 2.16 (supported) This definition does not belong to the simple subset, since the second argument f1+f2 of the constructor other's conclusion is not simple. It does however belong to the extended subset as described above.

```
inductive fibo(integer i, integer x) {
   case zero: fibo(0, 0);
   case one: fibo(1, 1);
   case other: \forall integer n, f1, f2;
        n>1 ==> fibo(n-1, f1) ==>
        \left nm2 = n-2; fibo(nm2, f2) ==> fibo(n, f1+f2);
}
```

The quantified variables f1 and f2 occurring in the complicated argument are both bound by the two preceding hypotheses: fibo(n-1, f1) binds f1 while fibo(nm2), f2) binds f2.

Note also that the chain of hypotheses is interrupted by a \let binding, which is permitted.

Example 2.17 (unsupported) This (nonsensical but correct) reformulation of the previous example is not in the subset of supported definitions.

```
inductive fibo(integer i, integer x) {
   case zero: \forall integer a; fibo(0, a+0-a);
   case one: \forall integer a; fibo(a+1-a, 1);
   case other: \forall integer n, f1, f2;
     n+f1>1+f1 ==> fibo(n-1, f1) ==> fibo(n-2, f2) ==> fibo(n, f1+f2);
}
```

Here we observe multiple problems:

- 1. In the zero constructor, a occurs in a complicated argument without having been bound by a hypothesis.
- 2. In the one constructor the first argument is complicated while it is the second argument that is complicated in the constructors zero and other.
- 3. In the other constructor, f1 occurs in a hypothesis before having been bound by the hypothesis fibo(n-1, f1)

2.6.4 Axiomatic definitions

EXPERIMENTAL

No difference with ACSL.

Figure 2.16 presents the grammar of axiomatic definitions.

```
logic-def
                            axiomatic-decl
    axiomatic-decl
                            axiomatic id { logic-decl* }
         logic-decl
                      ::=
                            logic-def
                            logic-type-decl
                            logic-const-decl
                            logic-predicate-decl
                            logic-function-decl
                            axiom-def
    logic-type-decl
                            type logic-type ;
        logic-type
                            id type-var-binders
                                                                polymorphic type
   logic-const-decl
                            logic type-expr poly-id ;
                      ::=
logic-function-decl
                            logic type-expr
                            poly-id parameters;
logic-predicate-decl
                            predicate
                            poly-id parameters?
        axiom-def
                            axiom poly-id : pred
```

Figure 2.16: Grammar for axiomatic declarations

Axiomatic definitions in all their generality are not monitorable. Therefore, future versions of this document will restrict them syntactically and/or through semantic criteria.

2.6.5 Polymorphic logic types

No difference with ACSL.

2.6.6 Recursive logic definitions

No difference with ACSL.

2.6.7 Higher-order logic constructions

EXPERIMENTAL

No difference with ACSL.

Figure 2.17 introduces new term constructs for higher-order logic.

```
      term ::= \lambda binders ; term
      abstraction

      | ext-quantifier (term , term , term )
      | term \with [range] = term }

      ext-quantifier ::= \max | \min | \sum |

      | \product | \numof
```

Figure 2.17: Grammar for higher-order constructs

Abstractions are only implemented for extended quantifiers, such as the term \sum(1, 10, \lambda integer k; k).

2.6.8 Concrete logic types

EXPERIMENTAL

No difference with ACSL.

Figure 2.18 introduces new constructs for defining logic types and the associated new terms.

2.6.9 Hybrid functions and predicates

No difference with ACSL.

Hybrid functions and predicates are usually difficult to implement, since they require the implementation of a memory model (or at least to support \at). Thus, most tools may not support them (or may support them partially).

2.6.10 Memory footprint specification: reads clause

EXPERIMENTAL

No difference with ACSL.

Figure 2.19 introduces reads clauses.

read clauses are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

2.6.11 Specification Modules

No difference with ACSL.

2.7 Pointers and physical adressing

No difference with ACSL.

Figure 2.20 shows the additional constructs for terms and predicates which are related to memory location.

2.7.1 Memory blocks and pointer dereferencing

No difference with ACSL.

All memory-related built-in functions and predicates are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

```
logic-def
                      type logic-type =
                ::=

Figure 2.20: Grammar extension of terms and predicates about memory

2.7.2 Separation

No difference with ACSL.

\separated is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.7.3 Dynamic allocation and deallocation

No difference with ACSL.

All these constructs are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

Figure 2.21 introduces grammar for dynamic allocations and deallocations.

Figure 2.21: Grammar for dynamic allocations and deallocations

2.8 Sets and lists

2.8.1 Finite sets

No difference with ACSL.

2.8.2 Finite lists

No difference with ACSL.

Figure 2.22 shows the notations for built-in lists.

2.9 Abrupt termination

No difference with ACSL.

Figure 2.23 shows the grammar of abrupt terminations.

2.10 Dependencies information

EXPERIMENTAL

No difference with ACSL.

Figure 2.24 shows the grammar for dependencies information.

Figure 2.22: Notations for built-in list datatype

```
abrupt-clause
                     ::=
                           exits-clause
       exits-clause
                     ::=
                           exits pred ;
abrupt-clause-stmt
                           breaks-clause | continues-clause | returns-clause
                           exits-clause
     breaks-clause
                           breaks pred ;
  continues-clause
                           continues pred ;
                     ::=
    returns-clause
                     ::=
                           returns pred ;
             term
                     ::=
                           \exit_status
```

Figure 2.23: Grammar of contracts about abrupt terminations

2.11 Data invariants

No difference with ACSL.

Figure 2.25 summarizes grammar for declarations of data invariants. strong invariants are unlikely evaluated efficiently at runtime.

2.11.1 Semantics

No difference with ACSL.

2.11.2 Model variables and model fields

No difference with ACSL.

Figure 2.26 summarizes the grammar for declarations of model variables and fields.

2.12 Ghost variables and statements

No difference with ACSL.

Figure 2.27 summarizes the grammar for ghost statements which is the same than the one of ACSL.

2.12.1 Volatile variables

Figure 2.28 summarizes the grammar for volatile constructs.

Figure 2.24: Grammar for dependencies information

Figure 2.25: Grammar for declarations of data invariants

2.13 Initialization and undefined values

No difference with ACSL.

\initialized is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

The FRAMA-C plug-in E-ACSL does not support labels as arguments of \initialized.

2.14 Dangling pointers

No difference with ACSL.

\dangling is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.15 Well-typed pointers

No such feature in E-ACSL: it would require the implementation of a C type system at runtime.

${\bf 2.16}\quad {\bf Preprocessing\ for\ ACSL}$

No difference with ACSL.

Figure 2.26: Grammar for declarations of model variables and fields

```
C-type-qualifier
                                                                   only in ghost
                               \ghost
                        ::=
    C-type-specifier
                               logic-type
           logic-def
                        ::=
                               ghost C-declaration
 C	ext{-}direct	ext{-}declarator
                                                                   function declarator
                               C	ext{-}direct	ext{-}declarator
                        ::=
                               (C-parameter-type-list?
                               ) /*@ ghost (
                               C-parameter-type-list
                                                                   with ghost params
                               ) */
C-postfix-expression
                               C-postfix-expression
                                                                   function call
                        ::=
                               ( C-argument-expression-list?
                               ) /*@ ghost (
                               C\hbox{-}argument\hbox{-}expression\hbox{-}list
                                                                   with ghost args
                               */
        C-statement
                        ::=
                               /*@ ghost
                               C-statement^+
                                                                  ghost code
                               */
                               if ( C-expression )
                               statement
                               /*@ ghost
                               else C-statement
                                                                   ghost alternative
                               C-statement*
                                                                   unconditional ghost code
                               */
                               /*@ ghost
C	ext{-}struct	ext{-}declaration
                               C-struct-declaration
                                                                   ghost field
                               */

Figure 2.28: Grammar for volatile constructs

Libraries

Disclaimer: this chapter is empty on purpose. It is left here to be consistent with the ACSL reference manual [2].

Conclusion

This document presents an Executable ANSI/ISO C Specification Language. It provides a subset of ACSL [2] implemented [3] in the Frama-C platform [7] in which each construct may be evaluated at runtime. The specification language described here is intended to evolve in the future in two directions. First it is based on ACSL which is itself still evolving. Second the considered subset of ACSL may also change.

Appendices

A.1 Changes

Version 1.22

- **Section 2.6.3:** add support for a subset of inductive definitions.

Version 1.21

– No changes: changes in ACSL 1.21 do not impact E-ACSL.

Version 1.20

– No changes: changes in ACSL 1.20 do not impact E-ACSL.

Version 1.19

- Update according to ACSL 1.19
 - Section 2.7.1: add the \object_pointer and \pointer_comparable built-in predicates.

Version 1.18

- No changes: changes in ACSL 1.18 do not impact E-ACSL.

Version 1.17

- **Section 2.2:** xor ^^ is not lazy.
- **Section 2.2:** new extended syntax for quantifications.
- Section 2.2.5: additional remark about real numbers and operations over them.
- **Section 2.3.4:** new extended syntax for set comprehensions.
- **Section 2.4.3:** more restrictive scoping rule for \at constructs.
- **Section 2.6:** add lemmas and data invariants.
- Section 2.6.3: add inductive predicates experimentally: the accepted subset will be refined in a future version.
- **Section 2.6.4:** add axiomatic declarations experimentally: the accepted subset will be refined in a future version.
- **Section 2.6.5:** add polymorphic logic types.
- Section 2.6.7: add higher-order logic constructions.
- **Section 2.6.8:** add concrete logic types.

- Section 2.6.10: add read clauses.
- **Section 2.10:** add dependencies information.
- **Section 2.12.1:** add volatile constructs.

Version 1.16

- Update according to ACSL 1.16
 - Section 2.3: add the check and admit clause kinds.
 - Section 2.4.1: add the check and admit clause kinds.
 - Section 2.4.2: add the check and admit clause kinds.
 - Section 2.4.2: add the check and admit clause kinds.

Version 1.15

- Update according to ACSL 1.15:
 - Section 2.12: add the \ghost qualifier.

Version 1.14

- Update according to ACSL 1.14:
 - Section 2.4.1: add the keyword check.

Version 1.13

- Update according to ACSL 1.13:
 - Section 2.3.4: add syntax for set membership.

Version 1.12

- Update according to ACSL 1.12:
 - **Section 2.3.4:** add subsections for build-in lists.
 - Section 2.4.4: fix syntax rule for statement contracts in allowing completeness clauses.
 - Section 2.7.1: add syntax for defining a set by giving explicitly its element.
 - Section 2.15: new section.

Version 1.9

- **Section 2.7.3:** new section.
- Update according to ACSL 1.9.

Version 1.8

- **Section 2.3.4:** fix example 2.6.
- $\bf Section~2.7:$ add grammar of memory-related terms and predicates.

Version 1.7

- Update according to ACSL 1.7.
- Section 2.7.2: no more absent.

Version 1.5-4

- Fix typos.
- **Section 2.2:** fix syntax of guards in iterators.
- **Section 2.2.2:** fix definition of undefined terms and predicates.
- **Section 2.2.3:** no user-defined types.
- **Section 2.3.1:** no more implementation issue for \old.
- **Section 2.4.3:** more restrictive scoping rule for label references in \at.

Version 1.5-3

- Fix various typos.
- Warn about features known to be difficult to implement.
- **Section 2.2:** fix semantics of ternary operator.
- **Section 2.2:** fix semantics of cast operator.
- **Section 2.2:** improve syntax of iterator quantifications.
- **Section 2.2.2:** improve and fix example 2.4.
- **Section 2.4.2:** improve explanations about loop invariants.
- Section 2.6.9: add hybrid functions and predicates.

Version 1.5-2

- **Section 2.2:** remove laziness of operator <==>.
- **Section 2.2:** restrict guarded quantifications to integer.
- **Section 2.2:** add iterator quantifications.
- **Section 2.2:** extend unguarded quantifications to char.
- **Section 2.3.4:** extend syntax of set comprehensions.
- Section 2.4.2: simplify explanations for loop invariants and add example...

Version 1.5-1

- Fix many typos.
- Highlight constructs with semantic changes in grammars.
- Explain why unsupported features have been removed.
- Indicate that experimental ACSL features are unsupported.
- Add operations over memory like \valid.
- **Section 2.2:** lazy operators &&, ||, ^^, ==> and <==>.
- **Section 2.2:** allow unguarded quantification over boolean.
- **Section 2.2:** revise syntax of \exists.
- **Section 2.2.2:** better semantics for undefinedness.
- **Section 2.3.4:** revise syntax of set comprehensions.
- **Section 2.4.2:** add loop invariants, but they lose their inductive ACSL nature.
- **Section 2.5.3:** add general measures for termination.
- **Section 2.6.11:** add specification modules.

Version 1.5-0

- Initial version.

A.2 Changes in E-ACSL Implementation

Version Gallium-31

- **Section 2.7.1:** support for \object_pointer.
- **Section 2.6.3:** add support for a subset of inductive definitions.

Version Chrome-24

- Section 2.6.7: support for \sum, \prod, and \numof.

Version Vanadium-23

- **Section 2.2:** mark logic function and predicate applications as implemented.
- **Section 2.3:** support for admit and check clauses.
- **Section 2.4.2:** support for loop variants.

Version Titanium-22

- **Section 2.2:** support for bitwise operations.
- **Section 2.2.7:** support for logic arrays.

Version Scandium-21

- **Section 2.2.5:** support for rational numbers and operations.
- Section 2.3: remove abrupt clauses from the list of exceptions.
- Section 2.3: support for complete behaviors and disjoint behaviors.
- Section 2.4.4: remove abrupt clauses from the list of exceptions.
- **Section 2.9:** add grammar for abrupt termination.

Version Potassium-19

- **Section 2.6:** support for logic functions and predicates.

Version Argon-18

- Section 2.4.3: support for \at on purely logic variables.
- Section 2.3.4: support for ranges in memory built-ins (e.g. \valid or \initialized).

Version Chlorine-20180501

- **Section 2.2:** support for \let binding.

Version 0.5

- **Section 2.7.3:** support for \freeable.

Version 0.3

- **Section 2.4.2:** support for loop invariant.

Version 0.2

```
Section 2.2: support for bitwise complementation.
Section 2.7.1: support for \valid.
Section 2.7.1: support for \block_length.
Section 2.7.1: support for \base_addr.
Section 2.7.1: support for \offset.
Section 2.14: support for \initialized.
```

Version 0.1

– Initial version.
