Foreword

This document describes version 1.19 of the E-ACSL specification language. It is based on the ACSL specification language [2]. Features of both languages may still evolve in the future, even if we do our best to preserve backward compatibility. In particular, some features are considered experimental, meaning that their syntax and semantics is not yet fixed. These features are marked with Experimental.

Acknowledgements

We gratefully thank all the people who contributed to this document: Patrick Baudin, Bernard Botella, Thibaut Benjamin, Loïc Correnson, Pascal Cuoq, Basile Desloges, Johannes Kanig, André Maroneze, Fonenantsoa Maurica, David Mentré, Benjamin Monate, Yannick Moy and Virgile Prevosto.

This work has been initially supported by the ‘Hi-Lite’ FUI project (FUI AAP 9).
This document is a reference manual for E-ACSL. E-ACSL is an acronym for “Executable ANSI/ISO C Specification Language”. It is an “executable” subset of ACSL [2] implemented [3] in the Frama-C platform [7]. Contrary to ACSL, each E-ACSL specification is executable: it may be evaluated at runtime.

In this document, we assume that the reader has a good knowledge of both ACSL [2] and the ANSI C programming language [8, 9].

1.1 Organization of this document

This document is organized in the very same way that the reference manual of ACSL [2]. Instead of being a fully new reference manual, this document points out the differences between E-ACSL and ACSL. Each E-ACSL construct which is not pointed out must be considered to have the very same semantics than its ACSL counterpart. For clarity, each relevant grammar rules are given in BNF form in separate figures like the ACSL reference manual does. In these rules, constructs with semantic changes are displayed in blue.

1.2 Generalities about Annotations

No difference with ACSL.

1.3 Notations for grammars

No difference with ACSL.
2.1 Lexical rules

No difference with ACSL.

2.2 Logic expressions

No difference with ACSL, but the quantifications must be guarded.

More precisely, the grammars of terms and binders presented respectively Figures 2.1 and 2.3 are the same than the ones of ACSL, while Figure 2.2 presents the grammar of predicates. The only differences introduced by E-ACSL with respect to ACSL are the fact that the quantifications that must be guarded and the introduction of iterators.

Quantification

The general form of quantifications (called generalized quantifications below), as described in Fig. 2.2, is restricted to a few finite enumerable types: the types of bound variables must be C integer types, enum types, pointer types, or their aliases.

Generalized quantification over large types (for instance, types containing 2^{32} elements), are unlikely evaluated efficiently at runtime.

In addition to generalized quantifications, a restricted form of guarded quantifications described in Fig. 2.4 is also recognized for (possibly infinite) enumerable types (typically, integer). In guarded quantifications, each bound variable must be guarded exactly once and, if its bounds depend on other bound variables, these variables must be guarded earlier or guarded by the same guard. Additionally, guards are limited to bound variables, meaning that the only allowed identifiers id are variable identifiers enclosed in the binder list.

Example 2.1 The following predicates are (labeled) guarded quantifications:

- sorted: \forall integer i, j; 0 <= i <= j < len ==> a[i] <= a[j]
- is_c: \exists u8 *q; p <= q < p + len && *q == (u8)c

Iterator quantification

For iterating over other data structures, E-ACSL introduces a notion of iterators over types that are introduced by a specific construct which attaches two sets — namely nexts and guards — to a binary predicate over a type τ. This construct is described by the grammar of Figure 2.5. For a type τ, nexts is a set of terms, and guards a set of predicates of the same cardinal. Each term in nexts is a function taking an argument of type τ and returning a value of type τ which is a successor of its argument. Each
2.2. LOGIC EXPRESSIONS

```
literal ::= \true | \false  \hspace{1em} \text{boolean constants}
        | integer  \hspace{1em} \text{(lexical) integer constants}

terms ::= term (, term)*
predicates ::= predicate (, predicate)*

Figure 2.5: Grammar of iterator declarations
2.2. LOGIC EXPRESSIONS

predicate in the set guards takes an element of type \( \tau \), and is valid (resp. invalid) to indicate that the iteration should continue on the corresponding successor (resp. stop at the given argument).

Furthermore, the guard of a quantification using an iterator must be the predicate given in the definition of the iterator. This abstract binary predicate takes two arguments of the same type. One of them must be unnamed by using a wildcard (character underscore '_'). The unnamed argument must be bound to the quantifier, while the other corresponds to the term from which the iteration begins.

**Example 2.2** The following example introduces binary trees and a predicate which is valid if and only if each value of a binary tree is even.

```c
struct btree {
    int val;
    struct btree *left, *right;
};
/*@ iterator access(_, struct btree *t):
@   nexts t->left, t->right;
@   guards \valid(t->left), \valid(t->right); */
/*@ predicate is_even(struct btree *t) =
@   \forall struct btree *tt; access(tt, t) ==> tt->val % 2 == 0; */
```

2.2.1 Operators precedence

*No difference with ACSL.*

Figure 2.6 summarizes operator precedences.

Figure 2.6: Operator precedence
2.2. LOGIC EXPRESSIONS

2.2.2 Semantics

No difference with ACSL, but undefinedness and same laziness than C.

More precisely, while ACSL is a 2-valued logic with only total functions, E-ACSL is a 3-valued logic with partial functions since terms and predicates may be “undefined”.

In this logic, the semantics of a term denoting a C expression $e$ is undefined if $e$ leads to a runtime error. Consequently the semantics of any term $t$ (resp. predicate $p$) containing a C expression $e$ leading to a runtime error is undefined if $e$ has to be evaluated in order to evaluate $t$ (resp. $p$).

Example 2.3 The semantics of all the below predicates are undefined:
- $1/0 == 1/0$
- $f(*p)$ for any logic function $f$ and invalid pointer $p$

Furthermore, C-like operators &&, ||, and _ ? _ : _ are lazy like in C: their right members are evaluated only if required. Thus the amount of undefinedness is limited. Consequently, predicate $p ==> q$ is also lazy since it is equivalent to $!p || q$. It is also the case for guarded quantifications since guards are conjunctions and for ternary condition since it is equivalent to a disjunction of implications.

Example 2.4 All the predicates below are well defined. The first, second and fourth predicates are invalid, whereas the third one is valid:
- \false && 1/0 == 1/0
- \forall integer $x$, -1 <= $x$ <= 1 ==> 1/x > 0
- \forall integer $x$, 0 <= $x$ <= 0 ==> \false ==> -1 <= 1/x <= 1
- \exists integer $x$, 1 <= $x$ <= 0 && -1 <= 1/0 <= 1

In particular, the second one is invalid since the quantification is in fact an enumeration over a finite number of elements, it amounts to 1/-1 > 0 && 1/0 > 0 && 1/1 > 0. The first atomic proposition is invalid, so the rest of the conjunction (and in particular 1/0) is not evaluated. The fourth one is invalid since it is an existential quantification over an empty range.

A contrario the semantics of the predicates below is undefined:
- 1/0 == 1/0 \false
- -1 <= 1/0 <= 1 ==> \true
- \exists integer $x$, -1 <= $x$ <= 1 && 1/x > 0

Furthermore, casting a term denoting a C expression $e$ to a smaller type $\tau$ is undefined if $e$ is not representable in $\tau$.

Example 2.5 Below, the first term is well-defined, while the second one is undefined.
- (char)127
- (char)128

Handling undefinedness in tools It is the responsibility of each tool which interprets E-ACSL to ensure that an undefined term is never evaluated. For instance, it may exit with a proper error message or, if it generates C code, it may guard each generated undefined C expression in order to be sure that they are always safely used.

This behavior is consistent with both ACSL [2] and mainstream specification languages for runtime assertion checking like JML [10]. Consistency means that, if it exists and is defined, the E-ACSL predicate corresponding to a valid (resp. invalid) ACSL predicate is valid (resp. invalid). Thus it is possible to reuse tools interpreting ACSL (e.g., FRAMA-C’s Eva [4] or Wp [1] in order to interpret E-ACSL, and it is also possible to perform runtime assertion checking of E-ACSL predicates in the same way than JML predicates. Reader interested by the implications (especially issues) of such a choice may read the articles of Patrice Chalin on that topic [5, 6].
2.3. FUNCTION CONTRACTS

2.2.3 Typing

No difference with ACSL.

2.2.4 Integer arithmetic and machine integers

No difference with ACSL.

2.2.5 Real numbers and floating point numbers

No difference with ACSL, but no quantification over real numbers and floating point numbers.

Exact real numbers and even operations over floating point numbers are usually difficult to implement. Thus, most tools may not support them (or may support them partially).

More precisely, most real numbers are not representable at runtime with an infinite precision. Consequently, most operations over them (e.g., equality) cannot be computed at runtime with an arbitrary precision. In such cases, it is the responsibility of each tool which interprets E-ACSL to specify the level of precision (e.g., $1e^{-6}$) up to which it is sound, and/or to emit undefined verdicts (e.g., “unknown”).

2.2.6 C arrays and pointers

No difference with ACSL.

Ensuring validity of memory accesses is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.2.7 Structures, Unions and Arrays in logic

No difference with ACSL.

Logic arrays without an explicit length are usually difficult to implement. Thus, most tools may not support them (or may support them partially).

2.3 Function contracts

No difference with ACSL, but no clause terminates.

Figure 2.7 shows the grammar of function contracts. This is a simplified version of ACSL one without terminates clauses. Section 2.5 explains why E-ACSL has no terminates clause.

2.3.1 Built-in constructs $\texttt{old}$ and $\texttt{result}$

No difference with ACSL.

Figure 2.8 summarizes the grammar extension of terms with $\texttt{old}$ and $\texttt{result}$.

2.3.2 Simple function contracts

No difference with ACSL.

assigns is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.3.3 Contracts with named behaviors

No difference with ACSL.
2.3. FUNCTION CONTRACTS

![Grammar of function contracts](image)

Figure 2.7: Grammar of function contracts

![\texttt{old} and \texttt{result} in terms](image)

Figure 2.8: \texttt{old} and \texttt{result} in terms
2.3.4 Memory locations and sets of terms

No difference with ACSL, but ranges and set comprehensions are limited in order to be finite.

Figure 2.9 describes the grammar of sets of terms. There are two differences with ACSL:

- ranges necessarily have lower and upper bounds;
- a guard for each binder is required when defining set comprehension. The requested constraints for guards are the very same than the ones for quantifications.

```
range ::= term .. term

tset ::= \emptyset            empty set
| tset -> id
| tset . id
| * tset
| & tset
| tset [ tset ]
| tset [ range ]
| ( range )    a range as a set of integers
| \union ( tset , tset)*   union of location sets
| \inter ( tset , tset)*   intersection of location sets
| tset + tset
| ( tset )
| ( tset | binders ; constraints ) set comprehension
| ( (term ,( term))* )    explicit set
| term                implicit singleton

pred ::= \subset ( tset , tset ) set inclusion
| term \in tset        set membership

constraints ::= guards (\&\& pred)
```

Figure 2.9: Grammar for sets of terms

**Example 2.6** The set \{ x | integer x; 0 <= x <= 10 \&\& x % 2 == 0\} denotes the set of even integers between 0 and 10.

2.3.5 Default contracts, multiple contracts

No difference with ACSL.

2.4 Statement annotations

2.4.1 Assertions

No difference with ACSL.

Figure 2.10 summarizes the grammar for assertions.

2.4.2 Loop annotations

No difference with ACSL, but loop invariants lose their inductive nature.

Figure 2.11 shows the grammar for loop annotations. There is no syntactic difference with ACSL.
2.4. STATEMENT ANNOTATIONS

<table>

Figure 2.11: Grammar for loop annotations
2.4. STATEMENT ANNOTATIONS

loop allocation and loop assigns are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

Loop invariants

The semantics of loop invariants is the same than the one defined in ACSL, except that they are not inductive. More precisely, if one does not take care of side effects (the semantics of specifications about side effects in loop is the same in E-ACSL than the one in ACSL), a loop invariant \( I \) is valid in ACSL if and only if:

- \( I \) holds before entering the loop; and
- if \( I \) is assumed true in some state where the loop condition \( c \) is also true, and if the execution of the loop body in that state ends normally at the end of the body or with a "continue" statement, \( I \) is true in the resulting state.

In E-ACSL, the same loop invariant \( I \) is valid if and only if:

- \( I \) holds before entering the loop; and
- if the execution of the loop body in that state ends normally at the end of the body or with a "continue" statement, \( I \) is true in the resulting state.

Thus the only difference with ACSL is that E-ACSL does not assume that the invariant previously holds when one checks that it holds at the end of the loop body. In other words a loop invariant \( I \) is equivalent to putting an assertion \( I \) just before entering the loop and at the very end of the loop body.

Example 2.7 In the following, \( \texttt{bsearch(t,n,v)} \) searches for element \( v \) in array \( t \) between indices 0 and \( n-1 \).

```c
/*@ requires n >= 0 && \valid(t+(0..n-1)); @
@ assigns \nothing; @
@ ensures -1 <= \result <= n-1; @
@ behavior success: @
@ ensures \result >= 0 ==> t[\result] == v; @
@ behavior failure: @
@ assumes t_is_sorted: \forall integer k1, int k2; @
@ 0 <= k1 < k2 <= n-1 ==> t[k1] <= t[k2]; @
@ ensures \result == -1 ==> @
@ \forall integer k; 0 <= k < n ==> t[k] != v; @*/

int bsearch(double t[], int n, double v) {
    int l = 0, u = n-1;
    /*@ loop invariant 0 <= l && u <= n-1; @*/
    while (l <= u) {
        int m = l + (u-l)/2; // better than (l+u)/2
        if (t[m] < v) l = m + 1;
        else if (t[m] > v) u = m - 1;
        else return m;
    }
    return -1;
}
```

In E-ACSL, this annotated function is equivalent to the following one since loop invariants are not inductive.
2.4. STATEMENT ANNOTATIONS

```c
/*@ requires n >= 0 && \valid(t+(0..n-1));
@ assigns \nothing;
@ ensures -1 <= \result <= n-1;
@ behavior success:
  @ ensures \result >= 0 ==> t[\result] == v;
@ behavior failure:
  @ assumes t_is_sorted : \forall integer k1, int k2;
  @ 0 <= k1 <= k2 <= n-1 ==> t[k1] <= t[k2];
  @ ensures \result == -1 ==> 
  @ \forall integer k; 0 <= k < n ==> t[k] != v;
@*/
int bsearch(double t[], int n, double v) {
  int l = 0, u = n-1;
  /*@ assert 0 <= l && u <= n-1;
  @ for failure: assert 
  @ \forall integer k; 0 <= k < n ==> t[k] == v ==> l <= k <= u;
  @*/
  while (l <= u) {
    int m = l + (u-l)/2; // better than (l+u)/2
    if (t[m] < v) l = m + 1;
    else if (t[m] > v) u = m - 1;
    else return m;
    /*@ assert 0 <= l && u <= n-1;
    @ for failure: assert 
    @ \forall integer k; 0 <= k < n ==> t[k] == v ==> l <= k <= u;
    @*/
  }
  return -1;
}
```

General inductive invariant

The syntax of this kind of invariant is shown Figure 2.12.

```plaintext
assertion ::= /*@ clause-kind' invariant pred ; */
            | /*@ for id (, id)*' : clause-kind' invariant pred ; */
```

Figure 2.12: Grammar for general inductive invariants

In E-ACSL, a general inductive invariant may be written everywhere in a loop body, and is exactly equivalent to writing an assertion.

2.4.3 Built-in construct \at

No difference with ACSL, but no forward references.

The construct \at(t, id) (where id is a regular C label, a label added within a ghost statement or a default logic label) follows the same rule than its ACSL counterpart, except that a more restrictive scoping rule must be respected in addition to the standard ACSL scoping rule:

- when evaluating \at(t, id) at a program point p, the program point p' denoted by id must be reached before p in the program execution flow; and
2.4. STATEMENT ANNOTATIONS

- when evaluating $\text{at}(t, \text{id})$, for each C left-value $x$ that contributes to the definition of a (non-ghost) logic variable involved in $t$, the equality $\text{at}(x, \text{id}) = \text{at}(x, \text{Here})$ must hold, i.e. the value of $x$ must not be modified between the program points $\text{id}$ and $\text{Here}$.

Below, the first example illustrates the first constraint, whereas the second example illustrates the second constraint.

**Example 2.8** In the following example, both assertions are accepted and valid in ACSL, but only the first one is accepted and valid in E-ACSL since evaluating the term $\text{at}(\ast(p+\text{at}(\ast q, \text{Here})), L1)$ at $L2$ requires to evaluate the term $\text{at}(\ast q, \text{Here})$ at $L1$: that is forbidden since $L1$ is executed before $L2$.

```c
/*@ requires \valid(p+(0..1)); */
/*@ requires \valid(q); */

void f(int *p, int *q) {
    *p = 0;
    *(p+1) = 1;
    *q = 0;
    L1: *p = 2;
    *(p+1) = 3;
    *q = 1;
    L2:
    /*@
    assert (\at(\ast(p+\text{at}(\ast q,L1)),\text{Here}) == 2); */
    /*@
    assert (\at(\ast(p+\text{at}(\ast q,\text{Here})),L1) == 1); */
    return ;
}
```

**Example 2.9** In the following example, the first assertion is supported, while the second one is not supported. Indeed, in the second assertion, the guard defining the logic variable $u$ depends on $n$ whose value is modified between $L1$ and $L2$.

```c
main(void) {
    int m = 2;
    int n = 7; ;
    L1: ;
    n = 4;
    L2:
    /*@
    assert \\
    \let k = m + 1; \\
    \exists integer u; 9 <= u < 21 \&\& \\
    \forall integer v; -5 < v <= (u < 15 ? u + 6 : k) ==> \\
    \at(n + u + v > 0, K); */ ; \\
    /*@
    assert \\
    \let k = m + 1; \\
    \exists integer u; n <= u < 21 \&\& // [u] depends on [n] \\
    \forall integer v; -5 < v <= (u < 15 ? u + 6 : k) ==> \\
    \at(n + u + v > 0, L1); */ ;
    return 0;
}
```

### 2.4.4 Statement contracts

No difference with ACSL.

Figure 2.13 shows the grammar of statement contracts.
2.5. Termination

No difference with ACSL, but no terminates clauses.

2.5.1 Integer measures

No difference with ACSL.

2.5.2 General measures

No difference with ACSL.

2.5.3 Recursive function calls

No difference with ACSL.

2.5.4 Non-terminating functions

No such feature in E-ACSL: whether a function is guaranteed to terminate if some predicate $p$ holds is not a monitorable property.

2.6 Logic specifications

No difference with ACSL.

Figure 2.14 presents the grammar of logic definitions.

2.6.1 Predicate and function definitions

No difference with ACSL.

2.6.2 Lemmas

No difference with ACSL.

Lemmas are verified before running the function main but after initializing global variables.
2.6. LOGIC SPECIFICATIONS

Figure 2.14: Grammar for global logic definitions
2.6. LOGIC SPECIFICATIONS

2.6.3 Inductive predicates

Experimental
No difference with ACSL.
Figure 2.15 presents the grammar of inductive predicates.

<table>
<thead>
<tr>
<th>Logic-def</th>
<th>::=</th>
<th>Inductive-def</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inductive-def</td>
<td>::=</td>
<td>Inductive poly-id parameters* { Inductive-case* }</td>
</tr>
<tr>
<td>Inductive-case</td>
<td>::=</td>
<td>Case poly-id : pred</td>
</tr>
</tbody>
</table>

Figure 2.15: Grammar for inductive predicates

Inductive predicates in all their generality are not monitorable. Therefore, future versions of this document will restrict them syntactically (e.g., to definite Horn clauses (http://en.wikipedia.org/wiki/Horn_clause) and/or through semantic criteria.

2.6.4 Axiomatic definitions

Experimental
No difference with ACSL.
Figure 2.16 presents the grammar of axiomatic definitions.

<table>
<thead>
<tr>
<th>Logic-def</th>
<th>::=</th>
<th>Axiomatic-decl</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Axiom-def</td>
<td>::=</td>
<td>Axiom poly-id : pred</td>
</tr>
</tbody>
</table>

Figure 2.16: Grammar for axiomatic declarations

Axiomatic definitions in all their generality are not monitorable. Therefore, future versions of this document will restrict them syntactically and/or through semantic criteria.
2.6.5 Polymorphic logic types

No difference with ACSL.

2.6.6 Recursive logic definitions

No difference with ACSL.

2.6.7 Higher-order logic constructions

Experimental

No difference with ACSL.

Figure 2.17 introduces new term constructs for higher-order logic.

| term | ::= | \lambda binders ; term abstraction |
|      |    | | ext-quantifier ( term , term , term ) |
|      |    | | | { term \with [ range ] = term } |

| ext-quantifier | ::= | \max | \min | \sum |
|               |    | \product | \numof |

Figure 2.17: Grammar for higher-order constructs

Abstractions are only implemented for extended quantifiers, such as the term \sum(1, 10, \lambda integer k; k).

2.6.8 Concrete logic types

Experimental

No difference with ACSL.

Figure 2.18 introduces new constructs for defining logic types and the associated new terms.

2.6.9 Hybrid functions and predicates

No difference with ACSL.

Hybrid functions and predicates are usually difficult to implement, since they require the implementation of a memory model (or at least to support \at). Thus, most tools may not support them (or may support them partially).

2.6.10 Memory footprint specification: reads clause

Experimental

No difference with ACSL.

Figure 2.19 introduces reads clauses.

Read clauses are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

2.6.11 Specification Modules

No difference with ACSL.
2.6. LOGIC SPECIFICATIONS

```
logic-def ::= type logic-type =
            logic-type-def ;
logic-type-def ::= record-type
                | sum-type
                | product-type
                | function-type
                | type-expr

record-type ::= { type-expr id
                ( ; type-expr id)∗ ;? }

function-type ::= ( ( type-expr
                (, type-expr )∗ )? )
                -＞ type-expr

sum-type ::= |? constructor
            ( | constructor)∗

constructor ::= id
              | id
              ( type-expr
              (, type-expr)∗ )

product-type ::= ( type-expr
                (, type-expr)∗ )

term ::= term . id
         | \match term
         { match-cases }
         | ( term (, term)∗ )
         | ( (. id = term ;)∗ )
         | \let ( id (, id)∗ ) =
         | term ; term

match-cases ::= match-case∗

match-case ::= case pat : term

pat ::= id
       | id ( pat (, pat)∗ )
       | pat | pat
       | _
       | literal | ( (. id = pat)∗ )
       | ( pat (, pat)∗ )
       | pat as id
```

Figure 2.18: Grammar for concrete logic types and pattern-matching
2.7. POINTERS AND PHYSICAL ADDRESSING

| Logic-function-decl ::= logic type-expr poly-id  
|                      | parameters reads-clause ; |
| Logic-predicate-decl ::= predicate poly-id  
|                        | parameters? reads-clause ; |
| Reads-clause ::= reads locations |
| Logic-function-def ::= logic type-expr poly-id  
|                      | parameters reads-clause = term ; |
| Logic-predicate-def ::= predicate poly-id  
|                        | parameters? reads-clause = pred ; |

Figure 2.19: Grammar for logic declarations with reads clauses

2.7 Pointers and physical addressing

No difference with ACSL.

Figure 2.20 shows the additional constructs for terms and predicates which are related to memory location.

| Term ::= null  
|          | base_addr one-label? ( term )  
|          | block_length one-label? ( term )  
|          | offset one-label? ( term )  
|          | allocation one-label? ( term )  
| Pred ::= allocable one-label? ( term )  
|         | freeable one-label? ( term )  
|         | fresh two-labels? ( term, term )  
|         | valid one-label? ( locations-list )  
|         | valid_read one-label? ( locations-list )  
|         | separated ( location, locations-list )  
|         | object_pointer one-label? ( locations-list )  
|         | pointer_comparable one-label? ( term, term )  
| One-label ::= { label-id }  
| Two-labels ::= { label-id, label-id } |

Figure 2.20: Grammar extension of terms and predicates about memory

2.7.1 Memory blocks and pointer dereferencing

No difference with ACSL.

All memory-related built-in functions and predicates are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).
2.7.2 Separation

_No difference with ACSL._

\`\texttt{\textbackslash separated}\` is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.7.3 Dynamic allocation and deallocation

_No difference with ACSL._

All these constructs are usually difficult to implement, since they require the implementation of a memory model. Thus, most tools may not support them (or may support them partially).

Figure 2.21 introduces grammar for dynamic allocations and deallocations.

\[
\begin{align*}
\text{allocation-clause} &::= \text{allocates dyn-allocation-addresses } ; \\
&\quad | \text{frees dyn-allocation-addresses } ; \\
\text{loop-allocation} &::= \text{loop allocates dyn-allocation-addresses } ; \\
&\quad | \text{loop frees dyn-allocation-addresses } ; \\
\text{dyn-allocation-addresses} &::= \text{locations}
\end{align*}
\]

Figure 2.21: Grammar for dynamic allocations and deallocations

2.8 Sets and lists

2.8.1 Finite sets

_No difference with ACSL._

2.8.2 Finite lists

_No difference with ACSL._

Figure 2.22 shows the notations for built-in lists.

2.9 Abrupt termination

_No difference with ACSL._

Figure 2.23 shows the grammar of abrupt terminations.

2.10 Dependencies information

\textit{Experimental}

_No difference with ACSL._

Figure 2.24 shows the grammar for dependencies information.
2.11. DATA INVARIANTS

| term ::= [ | | ] empty list |
| [ | | term (, term)* | ] list of elements |
| term ^ term list concatenation (overloading bitwise-xor operator) |
| term ^ term list repetition |

Figure 2.22: Notations for built-in list datatype

| abrupt-clause ::= exits-clause |
| exits-clause ::= exits pred ; |
| abrupt-clause-stmt ::= breaks-clause | continues-clause | returns-clause exits-clause |
| breaks-clause ::= breaks pred ; |
| continues-clause ::= continues pred ; |
| returns-clause ::= returns pred ; |
| term ::= \exit_status |

Figure 2.23: Grammar of contracts about abrupt terminations

2.11 Data invariants

No difference with ACSL.

Figure 2.25 summarizes grammar for declarations of data invariants.

Strong invariants are unlikely evaluated efficiently at runtime.

2.11.1 Semantics

No difference with ACSL.

2.11.2 Model variables and model fields

No difference with ACSL.

Figure 2.26 summarizes the grammar for declarations of model variables and fields.

2.12 Ghost variables and statements

No difference with ACSL.

Figure 2.27 summarizes the grammar for ghost statements which is the same than the one of ACSL.

2.12.1 Volatile variables

Figure 2.28 summarizes the grammar for volatile constructs.
2.13 Initialization and undefined values

No difference with ACSL.

\texttt{initialized} is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.14 Dangling pointers

No difference with ACSL.

\texttt{dangling} is usually difficult to implement, since it requires the implementation of a memory model. Thus, most tools may not support it (or may support it partially).

2.15 Well-typed pointers

No such feature in E-ACSL: it would require the implementation of a C type system at runtime.

2.16 Logic attribute annotations

No such feature in E-ACSL: logic attributes are implementation dependent; therefore their meaning cannot be guessed by a general-purpose (runtime) verification tool.

\texttt{logic-def} ::= model parameter ; \quad \text{model variable}
| model C-type-name \{ parameter ; \} ; \quad \text{model field}
### 2.16. LOGIC ATTRIBUTE ANNOTATIONS

Figure 2.28: Grammar for volatile constructs
2.17 Preprocessing for ACSL

No difference with ACSL.
Disclaimer: this chapter is empty on purpose. It is left here to be consistent with the ACSL reference manual [2].
This document presents an Executable ANSI/ISO C Specification Language. It provides a subset of ACSL [2] implemented [3] in the FRAMA-C platform [7] in which each construct may be evaluated at runtime. The specification language described here is intended to evolve in the future in two directions. First it is based on ACSL which is itself still evolving. Second the considered subset of ACSL may also change.
A.1 Changes

Version 1.19
- Update according to ACSL 1.19
  - Section 2.7.1: add the `object_pointer` and `pointer_comparable` built-in predicates.

Version 1.18
- No changes: changes in ACSL 1.18 do not impact E-ACSL.

Version 1.17
- Section 2.2: xor `^^` is not lazy.
- Section 2.2: new extended syntax for quantifications.
- Section 2.2.5: additional remark about real numbers and operations over them.
- Section 2.3.4: new extended syntax for set comprehensions.
- Section 2.4.3: more restrictive scoping rule for `at` constructs.
- Section 2.6: add lemmas and data invariants.
- Section 2.6.3: add inductive predicates experimentally: the accepted subset will be refined in a future version.
- Section 2.6.4: add axiomatic declarations experimentally: the accepted subset will be refined in a future version.
- Section 2.6.5: add polymorphic logic types.
- Section 2.6.7: add higher-order logic constructions.
- Section 2.6.8: add concrete logic types.
- Section 2.6.10: add `read` clauses.
- Section 2.10: add dependencies information.
- Section 2.12.1: add volatile constructs.

Version 1.16
- Update according to ACSL 1.16
  - Section 2.3: add the check and admit clause kinds.
  - Section 2.4.1: add the check and admit clause kinds.
  - Section 2.4.2: add the check and admit clause kinds.
A.1. CHANGES

Version 1.15
- Update according to ACSL 1.15:
  - Section 2.12: add the \texttt{ghost} qualifier.

Version 1.14
- Update according to ACSL 1.14:
  - Section 2.4.1: add the keyword \texttt{check}.

Version 1.13
- Update according to ACSL 1.13:
  - Section 2.3.4: add syntax for set membership.

Version 1.12
- Update according to ACSL 1.12:
  - Section 2.3.4: add subsections for build-in lists.
  - Section 2.4.4: fix syntax rule for statement contracts in allowing completeness clauses.
  - Section 2.7.1: add syntax for defining a set by giving explicitly its element.
  - Section 2.15: new section.

Version 1.9
- Section 2.7.3: new section.
- Update according to ACSL 1.9.

Version 1.8
- Section 2.3.4: fix example 2.6.
- Section 2.7: add grammar of memory-related terms and predicates.

Version 1.7
- Update according to ACSL 1.7.
- Section 2.7.2: no more absent.

Version 1.5-4
- Fix typos.
- Section 2.2: fix syntax of guards in iterators.
- Section 2.2.2: fix definition of undefined terms and predicates.
- Section 2.2.3: no user-defined types.
- Section 2.3.1: no more implementation issue for \texttt{old}.
- Section 2.4.3: more restrictive scoping rule for label references in \texttt{at}.

Version 1.5-3
- Fix various typos.
- Warn about features known to be difficult to implement.
- Section 2.2: fix semantics of ternary operator.
A.1. CHANGES

- **Section 2.2:** fix semantics of cast operator.
- **Section 2.2:** improve syntax of iterator quantifications.
- **Section 2.2.2:** improve and fix example 2.4.
- **Section 2.4.2:** improve explanations about loop invariants.
- **Section 2.6.9:** add hybrid functions and predicates.

**Version 1.5-2**

- **Section 2.2:** remove laziness of operator \(===>\).
- **Section 2.2:** restrict guarded quantifications to integer.
- **Section 2.2:** add iterator quantifications.
- **Section 2.2:** extend unguarded quantifications to char.
- **Section 2.3.4:** extend syntax of set comprehensions.
- **Section 2.4.2:** simplify explanations for loop invariants and add example.

**Version 1.5-1**

- Fix many typos.
- Highlight constructs with semantic changes in grammars.
- Explain why unsupported features have been removed.
- Indicate that experimental ACSL features are unsupported.
- Add operations over memory like \(\valid\).
- **Section 2.2:** lazy operators \&\&, ||, ^^, => and \(===>\).
- **Section 2.2:** allow unguarded quantification over boolean.
- **Section 2.2:** revise syntax of \(\exists\).
- **Section 2.2.2:** better semantics for undefinedness.
- **Section 2.3.4:** revise syntax of set comprehensions.
- **Section 2.4.2:** add loop invariants, but they lose their inductive ACSL nature.
- **Section 2.5.2:** add general measures for termination.
- **Section 2.6.11:** add specification modules.

**Version 1.5-0**

- Initial version.
